BPMN 2.0 Business Process Model and Notation

Complete Element Set

Pools and Lanes

A Pool is used to define a group of Participants such as an area within an organization or an external entity that collaborates within a process. A process model is normally created from the perspective of a single participant – the White Box Pool, and contains the detail of that process. Black Box Pools are considered external to the scope of the process (although not necessarily outside of the organization), and do not show flow and activities. Black box pools may be collapsed and rotated, but do not have to be.

A Lane is used to define a specific participant or role within a process. A lane may be contained within a pool or may itself be broken down into other lanes.

Activities

Within the flow of a process, one or more lanes will perform a number of activities.

A Task is something that a lane (role) does during the process. A task is a granular (atomic) activity that cannot or does not need to be broken down any further.

A Sub Process summarizes a group of activities, and can be expanded out into further detail. Sub processes can be shown as collapsed (with the [-] symbol), or expanded.

Tasks

Sub Processes

Flows

Message Flow is the flow of information in messages between Participants.

Sequence Flow is the flow of the process between events that occur, activities performed by the lanes and decisions that are made (gateways).

Associations are used to attach artifacts (such as data objects) to activities.

Artifacts

Data Objects are inputs to and outputs from activities. Data objects could be used to represent documents, data or other objects that are passed between the activities in a process.

A Data Store is somewhere that the process can read or write data, that persists beyond the scope of the process.

A Message is used to depict the contents of a communication between 2 participants.

A Group is a visual way of informally grouping items on a diagram, for example to highlight an area that requires further analysis.

Annotations allow additional information relevant in documenting the process to be shown on the diagram.

Events

An Event is an indicator that something has happened within a process.

A process begins with a Start Event indicating something has happened, such as a message received or a data that has been reached.

Intermediate Events happen within the flow of the process (between start and end events).

A process finishes with an End Event. Because a process may have several outcomes, there may be multiple events and messages.

Gateways

A Parallel Gateway is used to synchronize parallel flows and to create parallel flows.

The Complex Gateway can be used to model complex synchronization behavior, not captured by other gateways.

The Event-Based Gateway represents a branching point in the Process where the alternative paths that follow the Gateway are based on Events that occur, rather than the evaluation of Expressions using Process data (as with an Exclusive or Inclusive Gateway).
